Summary:
This work reports on the design and measurement results of a circular waveguide sensor filled with dielectrics tuned at 5.6 GHz for online process monitoring applications of low loss liquids and mixtures of liquids with liquids or air. Connecting the sensor to a Universal Software Radio Peripheral (USRP), an online mass flow meter is realized, that can simultaneously detects the concentration and velocity for liquid/air mixtures.

Keywords: circular waveguide sensor, cavity perturbation technique, low dielectric materials, concentration measurements, velocity measurements, online measurement

Introduction
Real-Time Monitoring of liquids using microwave signals became a growing interest recently. Applications can be found in food, oil and pharmaceutical industries, especially when a non-invasive technology is mandatory [1]. For permittivity extraction, the cavity perturbation method was applied [2]. Changing the material inside the sensor causes a shift in the resonant frequency that is directly related to the dielectric constant of the liquid or liquid/air concentration. Additionally, the velocity of the liquid can be detected by applying the spatial microwave velocimetry [3]. The sensor is attached to a Universal Software Radio Peripheral Ettus B210 [4] to enable online measurements at microwave frequencies.

Sensor Design
The microwave sensor, shown in Fig. 1, consists of a resonant configuration of two cavities made of Rogers RT/duriod 5880 substrates and a PTFE pipeline.

Concentration measurement
A change in the permittivity or the concentration of liquids or liquid/air mixtures in the measurement section causes a change in the resonant frequency. Due to the fact that liquid/air mixtures absorb energy from the sensor, attenuation of the transmitted signal occurs. This effect can be measured by the complex transmission type S-parameter $S_{21}$.

In order to extract the value of the dielectric constant, a sensor prototype was operated by the two-port vector network analyser HP 8722.

Fig.1. Microwave sensor exploded drawing and Transversal Magnetic (TM) modes

The coupling of the microwave sensor to an external circuitry is applied using two H-field probes that are located parallel to the material flow. Transversal Magnetic (TM) modes are excited in the flow direction in the measurement section. To obtain two symmetrical transmission maxima inside the pipeline only one fully copper disc is used in the middle of the sensor.

Concentration measurement
A change in the permittivity or the concentration of liquids or liquid/air mixtures in the measurement section causes a change in the resonant frequency. Due to the fact that liquid/air mixtures absorb energy from the sensor, attenuation of the transmitted signal occurs. This effect can be measured by the complex transmission type S-parameter $S_{21}$.

In order to extract the value of the dielectric constant, a sensor prototype was operated by the two-port vector network analyser HP 8722.

Fig.2. Simulated and measured results of the transmission $S_{21}$ with air/sunflower oil dielectric (preliminary results)
RF-simulations using CST Microwave were conducted using sunflower oil with a permittivity of 2.3 and low losses at 5.6 GHz.

Two transmission maxima (TM₀₁₀ and TM₀₁₁) were measured with this sensor configuration as shown in Fig. 1 and Fig. 2. The comparison of the empty sensor and the oil-filled sensor at the fundamental TM₀₁₁ mode shows a frequency shift of nearly 73 MHz for measurement and simulation. The observed frequency deviation between simulation and measurement for the TM₀₁₀ mode is related to the assembly of the sensor and tolerance of the parts. Additionally, the oil measurement shows a higher attenuation, compared to the simulated results. The results of frequency shift air/oil are summarized in Tab.1.

**Velocity measurement**

In order to extract the velocity of liquids or liquid/air mixtures particles with the microwave sensor, measurement results versus time are analysed [3]. If a dielectric droplet enters in the measurement section the phase of the transmitted RF signal S₂₁ describes a squared sinusoidal signal.

Fig. 3 shows the time depending amplitude and phase when a water droplet travels through the sensor. There are two sinusoidal half-waves. The amplitude of the half-waves depends on the position of the droplet inside the sensor measured section.

**Online Measurements**

Fig. 4 depicts the fabricated microwave sensor and a block diagram of the USRP Module.

**Conclusion**

The implementation of a microwave dielectric mass flow sensor for online monitoring without disturbance of the flow distribution was shown. The first prototype exhibits promising results for precise simultaneous concentration and velocity detection of low dielectric liquids and liquid/air mixtures.
