Abstract
In this work, we synthesized phosphorus-decorated MoS₂ thin films as material for gas sensor through a solution process and chemical vapor deposition. Phosphorus-decorated MoS₂ showed the higher gas sensing performance than the bare MoS₂ thin films. With this method, higher sensitivity and selectivity can be achieved, resulting in the broad application of MoS₂-based gas sensors.

Key words: Gas sensors, 2D TMDs, MoS₂ thin film, phosphorus, Internet of Things

Introduction
In recent days, internet of things (IoT) has increased enormous attentions and one of the most arising research areas on IoT is the gas sensor. The gas sensors play an essential role in various fields. To meet IoT requirements, the ease of integration of electronic circuits with low cost, small size and high sensing performances are crucial for gas sensors [1]. Among various types of gas sensors, chemoresistive gas sensors based on semiconductors have been considered as most applicable candidates for the IoT because of their low cost and small size [2].

Two-dimensional (2D) materials are noteworthy because their characteristics, such as high surface-to-volume ratios and easy device fabrication are suitable to be applied as the active material of the gas sensors [3]. Since many transition metal disulfides, such as MoS₂, WS₂ and SnS₂, are semiconducting with tunable bandgap energies depending on the thickness, the transition metal disulfides are inherently more desirable than graphene, metallic with zero band gap energy, for chemoresistive gas sensing applications [4]. In particular, MoS₂ exhibited impressive gas sensing performances due to its high surface-to-volume ratio, semiconducting properties, and plentiful active edge sites [5]. However, despite the increased interest and the diverse studies, the study of the relationship between the gas detection mechanism and the edge sites of 2D MoS₂ have not been clarified. Therefore, in order to discover the specific sensing mechanism, we synthesized phosphorus-decorated MoS₂ by the chemical vapor deposition (CVD) method and solution process. Since the MoS₂ is the 2D material, the decoration effect is expected to be higher than 3D materials. Therefore, decorating the MoS₂ thin films with various materials can lead to unpredicted unique results.

Method
Pt interdigitated electrodes (IDE) were prepared and used as substrates for the sensor applications. The phosphorus-decorated MoS₂ thin films were synthesized on the 1 mm x 1 mm size active area on the Pt IDE. The solution process and the CVD process were used to synthesize the P-decorated MoS₂ thin films.

The sensing performances of the gas sensor based on the P-decorated MoS₂ thin films were measured in a gas measuring device with a quartz tube and a furnace. The variations of the resistance were measured while the flowing gases were changing from dry air to the target gases with a source measurement unit. The mass flow controllers controlled the exact amount of gas flow, maintaining the constant flow rate of 1000 sccm.

Results and Discussion
Fig. 1 shows the response curves to 50 ppm C₂H₅OH at 250 °C for MoS₂ and phosphorus-decorated MoS₂. Compared with the gas sensor based on the bare MoS₂ thin films, the gas sensor based on the P-decorated MoS₂ thin...
films showed 50 times higher response for C₂H₅OH detection.

Fig. 1. Response curves of bare MoS₂ and phosphorus-decorated MoS₂ thin films to 50 ppm C₂H₅OH at 250°C.

Fig. 2 shows the responses of the P-decorated MoS₂ thin films to 50 ppm C₂H₅OH, CH₃CHO, C₆H₆, H₂, CH₃COCH₃, and 5 ppm NO₂ at 250 °C.

The response of the sensor was calculated by eq. (1),

$$\frac{R_{\text{gas}} - R_{\text{air}}}{R_{\text{air}}} = \Delta R/R_0$$  (1)

Where, $R_{\text{air}}$ is the base resistance of the gas sensor in air condition and $R_{\text{gas}}$ is the resistance when the target gas was fully adsorbed. The sensor showed the second highest response to CH₃CHO and the response to C₂H₅OH was three times higher than the response to CH₃CHO. These results indicate that the P-decorated MoS₂ thin film is beneficial for the selective C₂H₅OH detection.

**Conclusion**

We have investigated gas sensors based on phosphorus-decorated MoS₂ thin films. The dangling bonds and base resistances were changed by the phosphorus atoms, resulting in the variation of the sensing performances. The sensor has the highest response to C₂H₅OH and the selective characteristic at 250 °C. Since the MoS₂ is the 2D material, more unprecedented sensing properties can be studied with the additional noble metal decoration which can broaden the potential of MoS₂-based gas sensors.
